

Company

Hierarchical Inheritance is when two or more child classes inherit from the same parent class.

Each child class gets access to all the methods and variables of the parent class.

But each child can also define its own unique methods or behavior.

```
// Parent class
class Employee {
    public void work() {
        System.out.println("Employee is working...");
    }
}

// Child class 1
class Developer extends Employee {
    public void writeCode() {
        System.out.println("Developer is writing code...");
    }
}

// Child class 2
class Tester extends Employee {
    public void testSoftware() {
        System.out.println("Tester is testing software...");
    }
}
```

```
// Main class
public class Main {
    public static void main(String[] args) {
        // Developer object
        Developer dev = new Developer();
        dev.work(); // inherited method
        dev.writeCode(); // specific to Developer

        // Tester object
        Tester tester = new Tester();
        tester.work(); // inherited method
        tester.testSoftware(); // specific to Tester
    }
}
```
